

## CLL:113 Tut-9

The concentration distribution of a reactant undergoing second order reaction in a plug flow reactor is given by the differential equation.

$$\frac{dy}{d\tau} = -y^2$$

Where

$y = \frac{C}{C_0}$  and  $\tau = \frac{kVC_0}{F}$  with the initial condition at  $\tau = 0, y = 1$

A. Evaluate and plot the non dimensional concentration profile with non dimensional time  $\tau$  by

- (1) Explicit Euler Method
- (2) Crank Nicholson Method
- (3) Implicit Euler method

Each for 5 time steps 0.1, 0.2, 0.5, 1 and 2.

In the three plots that you submit for this question also provide the analytical result.

B. Also provide a comparative graph to show how the relative percentage error varies with  $\tau$  for all the methods for time step 0.5.

C. Give reasoning for the graphs and submit a doc file with all the results and submit the code(s) separately.
